

Spontaneous potential anomalies in and around the outcrop of the marine clay

Kunihiro Ryoki [1]

[1] Natural Sci. Osaka PC

The potential distribution measurement was done in the marine clay layer distribution region of the Osaka group. When the measurement results are compared with the geologic map, the distribution of the marine clay was well accord with the low potential zone. On the other hand, it was thought that the low potential zone did not depend on geographical features in the investigation region when the measurement results were compared with geographical features.
