

Fluid flow in the decollement zone, the Nago Formation in the Shimanto Belt, Okinawa Island

Shinya Sakata[1]

[1] Geology Sci., Kochi Univ

The fluid inclusion study within the vein minerals clues to understand the fluid flow of the accretionary complex. As a result, the rocks suffered the two stages from deformation of the underthrusting to the intra-prism shortings in the Shimanto accretionary complex, Okinawa Island. The fluid inclusion analysis revealed that the H₂O-rich fluid was flown slow speed that the vein crystals have euhedral shape under the condition of 255C/130MPa to 340C/270MPa. It was succeed that the quantitative discussion between the structural and thermal evolution of the ancient decollement zone.
