Based on the GCITEM-IGGCAS model and tides from TIMED/SABER observations, the longitudinal variations of the E-region plasma densities, which is induced by non-migrating tides, are investigated. We simulated the intra-annual variation of the E-region plasma density, and found that equinoctial E-region plasma density shows an obvious wavenumber-4 longitudinal structure both in Equinox and in June Solstice, and a wavenumber-3 longitudinal structure in December Solstice. Our simulations suggest that DE3 tide can drive the wavenumber-4 structure in E-region plasma density, and DE2 tide can drive the wavenumber-3 structure. O<sub>2</sub><sup>+</sup> controls the longitudinal variations of total ions density at lower E-region, and NO<sup>+</sup> mainly controls that at higher E-region. We also noticed that the longitudinal variations of O<sub>2</sub><sup>+</sup> and of NO<sup>+</sup> show obvious phase differences.
