熱帯インド洋におけるダイポールモード現象と季節内変動との相互作用
Possible interactions between Indian Ocean Dipole and intraseasonal variability in the tropical Indian Ocean

升本 順夫 [1*]
Yukio Masumoto[1*]

[1] 海洋研究開発機構
[1]JAMSTEC

Variations in the tropical Indian Ocean cover a wide range of spatial and temporal scales. Indian Ocean Dipole (IOD) is one of the dominant interannual climate modes there, and several intraseasonal variations are believed to have interaction with IOD through oceanic bridges and/or air-sea interactions. Two of such examples will be explored in this presentation.

The first example is influence of meso-scale ocean eddy activity in the southeastern tropical Indian Ocean, which is generated by baroclinic instability in the northern part of the South Equatorial Current. Strong meridional temperature gradient associated with the IOD event results in anomalously energetic eddy activity. This causes stronger-than-normal northward eddy heat transport, which tends to reduce the meridional temperature gradient, hence a negative feedback on the IOD event itself.

Another example is impact of intraseasonal equatorial Kelvin waves on initiation of the IOD events, particularly in 2006 case. During May to August, before the 2006 IOD event, several upwelling equatorial Kelvin waves were excited by easterly wind anomalies in the equatorial central Indian Ocean. Negative subsurface temperature anomalies at the thermocline depth appeared associated with penetration of these Kelvin waves along the Sumatra coast, creating favorable conditions for cooling of the surface layer due to monsoonal upwelling in August. Constructive interaction between the two processes may set a critical condition for the generation of the 2006 IOD.

Such scale-interactions in the tropical Indian Ocean should be investigated in more detail for better understanding of mechanisms responsible for the IOD evolution and the skillful prediction of IOD.

The sea surface temperature (SST) in the upwelling region along the western boundary of the Arabian Sea is known to influence the Indian summer monsoon rainfall. In this study, we examine how a reflection of semiannual Kelvin waves, which is forced by westerly winds during monsoon breaks and accompanied by the Yoshida-Wyrtki Jet, may influence this region based on ocean general circulation model experiments. When results from two experiments with and without a damping near the eastern equatorial Indian Ocean are compared, the SST in the western Arabian Sea becomes colder by as much as 0.4 degree C in the latter experiment. By calculating mixed layer heat balance, it is shown that this SST difference is mainly due to a difference in horizontal advection, but is damped by surface heat flux.

The role of air sea interaction in the diurnal variations of convective activity during the suppressed and developing stages of an intraseasonal convective event is analyzed using in situ observations from the Mirai Indian Ocean cruise for the Study of the Madden Julian oscillation (MJO)-convection Onset (MISMO) experiment. For the whole period, convection shows a clear average diurnal cycle with a primary maximum in the early morning and a secondary one in the afternoon. Episodes of large diurnal sea surface temperature (SST) variations are observed because of diurnal warm layer (DWL) formation. When no DWL is observed, convection exhibits a diurnal cycle characterized by a maximum in the early morning, whereas when DWL forms, convection increases around noon and peaks in the afternoon. Boundary layer processes are found to control the diurnal evolution of convection. In particular, when DWL forms, the change in surface heat fluxes can explain the decrease of convective inhibition and the intensification of the convection during the early afternoon.

This study investigates space-time variations of the tropical convective activities and temperatures around the tropical tropopause associated with the intraseasonal oscillation (ISO) during the southern summer by using outgoing longwave radiation (OLR) data from the National Oceanic and Atmospheric Administration and atmospheric fields from the European Centre for Medium-range Weather Forecasts Interim reanalysis data.

Cluster analysis is conducted in order to classify ISO types according to both the phase speed and the longitudinal extent of the eastward propagation. In performing cluster analysis we use the locus of convective activities observed in the unfiltered OLR data by retaining both the ISO and seasonal mean components to investigate interaction between the two. Then, the 72 ISO events in the 32 southern summers are mainly grouped into four clusters. Two of the clusters exhibit the slow (<2 m/s) propagation speed in the unfiltered OLR field and the others fast (˜4 m/s). One cluster characterized as the El Nino phase has the fast speed while passing over the date line and another as the La Nina phase has the slow speed while propagating to ˜120E. Compared with the other two clusters characterized as the weak El Nino-Southern Oscillation phase, the speed is slow while propagating to ˜135E when the SSTs over the Western Pacific are relatively low.

Low temperatures around the tropical tropopause appear to the east of the eastward-propagating convection in the tropics and to the west in the subtropics, forming a horseshoe-shaped structure. The strength of the horseshoe-shaped temperature structure is determined by that of the convective activities. Furthermore, the strength and location of the 100-hPa temperature minima differ among the clusters. This study implies that the different ISOs would cause different impacts on the dehydration process in the tropical tropopause layer depending on their types.

Based on Global ELF observation Network (GEON) and Outgoing Longwave Radiation (OLR) intensity, we carried out a correlated analysis between the number of the lightning strokes and cloud variation in the tropical regions, focusing the variation around one month periodicity. It was found that the number of lightning stokes in the Maritime Continent (MC) varies with about month periodicity in the period from February to June 2004 and shows positive correlation (R= ?0.8) with OLR in the Western Paci?c Warm Pool (WPWP). That is, when thunderstorm activity in the MC is enhanced, the OLR in WPWP becomes large, meaning less cloud amount. On the other hand, OLR in the central Africa shows negative correlation with the number of lightning stokes in the MC in that period (R= ?-0.7). Furthermore, in the central Africa OLR seems to re?ect the number of lightning strokes, showing good correlation between them. This implies that the activities of thunderstorms both in the central Africa and in the MC oscillate in the same phase. Such a synchronization of thunderstorms or cloud amount in global scale without phase difference has not been reported and seems difficult to explain these phenomena by conventional theories. We may need to consider the variation of solar activity, such as UV or galactic cosmic rays, whose variation in the present period (Feb-Jun 2004) shows good correlation with OLR variations in tropical region.

1. Introduction

Knowledge of the lightning activity is an important tool to the meteorologists. Many literatures have discussed on lightning activity for different regions. However, the studies pertaining to the variability of lightning occurrences in the equatorial Indonesia are scanty, except a few studies. Hence, in the present study, the variability of lightning activity in the equatorial Indonesia is examined, particularly at Kototabang (KT; 100.32E, 0.20S), Pontianak (PT; 109.37E, 0.00S), Manado (MN; 124.92E, 1.55N) and Biak (BK; 136.10E, 1.18S).

2 Data and Methodology

Lightning activity are observed from theWorld Wide Lightning Location Network (WWLLN) data. Following the advice of the WWLLN developers, only those lightning locations that triggered at least five sensors and that had residuals $<$ 30 ms are included in this analysis [1]. The surface precipitation and the profiles of hydrometeors and latent heating are obtained from the products of the Tropical Rainfall Measuring Mission (TRMM) satellite. The aerosol data are retrieved from the Moderate Resolution Imaging Spectroradiometer (MODIS). Raindrop size distribution (DSD) at the surface is from a network of Parsivel disdrometers. 1.3 GHz wind profiler data at the four sites are used to determine the precipitating cloud type.

3 Results

The evidence of regional variation of precipitation microstructure (e.g., DSD) is clearly observed, and become more obvious during heavy rain. The composite spectra of PT and KT were much broader than Marshall-Palmer distribution, in contrast to the DSD at MN and BK, where the DSDs were narrow. This characteristic is consistent with the lightning activity. Figure shows regional variability of percentage occurrence of flashes. The convective storms are more intense at PT than other three sites and produce larger raindrops. Detailed analysis regarding the relationships among lightning, precipitation, and hydrometeor characteristics in equatorial Indonesia will be presented in the meeting.

Summer climate in the Northwestern Pacific (NWP) displays large year-to-year variability, affecting densely populated Southeast and East Asia by impacting precipitation, temperature and tropical cyclones. The Pacific-Japan (PJ) teleconnection pattern provides a crucial link from the tropics of high predictability to East Asia. Using coupled climate model experiments, we show that the PJ pattern is the atmospheric manifestation of an air-sea coupled mode spanning the Indo-NWP warm pool. In this coupled mode, the PJ pattern forces the Indian Ocean (IO) via a westward propagating atmospheric Rossby wave. In response, IO sea surface temperature (SST) feeds back and reinforces the PJ pattern via a tropospheric Kelvin wave. Ocean coupling increases both the amplitude and temporal persistence of the PJ pattern. Cross-correlation of ocean-atmospheric anomalies confirms the coupled nature of this PJIO mode. El Nino-Southern Oscillation (ENSO) is a major external driver of the PJIO mode, leaving the last echoes of ENSO in the IO-NWP in the form of this mode. We further demonstrate that the PJIO mode is indeed highly predictable, giving hopes for skillful seasonal forecast over the densely populated region.

MIROC5 を用いた季節予測システムにおける 2 タイプのエルニーニョの予測可能性
Recent progress in the MIROC5 seasonal prediction system and predictability of two flavors of El Nino

今田 由紀子 [1*]
Yukiko Imada[1*]

[1] 東京大学大気海洋研究所
[1]Atmosphere and Ocean Research Institute, the University of Tokyo

This study investigates the difference of the seasonal predictability for two prominent types of El Nino, traditional eastern Pacific (EP) events and central Pacific (CP) events.

We developed a seasonal prediction system using the coupled atmosphere-ocean general circulation model (AOGCM) MIROC5 co-developed by Atmosphere and Ocean Research Institute (AORI), National Institute for Environmental Studies (NIES), and Japan Agency for Marine-Earth Science and Technology (JAMSTEC). The spatial resolution is a horizontal triangular spectral truncation at total wave number 85 (T85) with 40 vertical layers, and eight ensemble forecast members are generated according to the protocol of the WCRP Climate-system Historical Forecast Project (CHFP). Hindcast products for the period 1979-2011 show high predictability of tropical climate signals with the significant anomaly correlation coefficient skill scores, even though the ocean anomaly data assimilation is applied to the initialization process. The monsoon and Indian Ocean Dipole (IOD) indices also show predictable signals until a few months later. Interestingly, our seasonal prediction system is less affected by the ”spring prediction barrier” compared to most of the other AOGCMs.

We assess the difference of the seasonal predictability for two prominent types of El Nino, traditional EP events and recent CP events. Overall, the predictable months of CP events are shorter than EP events because CP events have less amplitude and are sensitive to atmospheric noises. It seems that this difference in predictability connects to the recent low predictability after 2000 as shown in Barnston et al. (2012). Characteristics of each error-growing process are also investigated.

We investigate oceanic and atmospheric variations related to coastal upwelling along New Guinea Island north coast before onset of El Nino event. In our previous studies, existence of the coastal upwelling and related SST cooling near New Guinea Island during December 2001 to January 2002, which was prior to onset of 2002/03 El Nino event, were shown by observational data. Furthermore, we explored cooling mechanism related to the coastal upwelling using high-resolution OGCM (OFES) hindcasts using NCEP/NCAR forcing and QuikSCAT forcing during 1981-2010. In this study, we analyze long-term output of 200-year simulation of high-resolution air-sea coupled general circulation model (SINTEX-F ver2). SST patterns similar to the observed coastal upwelling along north coast of New Guinea Island appear before onset of El Nino-like events in the SINTEX-F ver2 simulation. At those periods, positive zonal SST gradients in the western equatorial Pacific also appear in association with the SST cooling near New Guinea Island. Relatively strong westerly surface winds, which are expected by the positive SST zonal gradients, also appear in those periods. Such oceanic and atmospheric relationship is similar to that of observation for SST cooling period of December 2001 to January 2002. It might suggest that the SST cooling along north coast of New Guinea Island can relates to El Nino onset via atmospheric changes. We will also explore upper-ocean structure during the SST cooling period to further explore a relationship between the SST cooling pattern and New Guinea Island coastal upwelling before El Nino onsets using the SINTEX-F ver2 simulation.

Regional climate modeling is an effective way to study on phenomena which found interesting in global GCMs. Regional models can play a complementary role to global models in experimental designs. While global models are free running, but may suffer from biases, regional models are bounded at lateral boundaries and achieve better realism.

Using the data of observations and global models, Hasegawa et al (2009, 2010, 2011) found strong northwesterly surface winds and cold-water upwellings along the northern coast of New Guinea often occur before El Nino onsets. They hypothesized that the cold waters generate positive zonal sea surface temperature (SST) gradient together with high SST east of the warm pool in the Western Pacific Ocean contribute to enhancement of the westerly surface winds, leading to onsets of El Nino events. The goal is to understand this region in an ocean-atmosphere coupled system. As a first step, we have conducted experiments with a regional atmospheric model. The model used in this study is the International Pacific Research Center (IPRC) Regional Atmospheric Model (iRAM) to understand the effects of the cold SST. The model covers the western Pacific Ocean with a horizontal resolution of 0.25 degree. We particularly focused on December 2001 to January 2002, as Hasegawa et al. (2009) did in their diagnostic study. The model well reproduced events of wind westerly surface winds in this region. Experiments show that wind variations near the New Guinea are responsive to local SST. Even when the lateral boundary condition is unchanged, westerly surface wind is weakened when the cold signal by the upwelling is eliminated from the SST field. We also pay attention to the role of the high mountains of New Guinea in shaping climate around this region. An experiment showed the orography of New Guinea causes rising air motion above the mountains. Recent experiments of the coupled ocean-atmospheric model (coupled to the HYbrid Coordinate Ocean Model using the Earth System Modeling Framework) will be also reported.

[1]Research Institute for Global Change, JAMSTEC, [2]Earth Simulator Center, JAMSTEC, [3]Application Laboratory, JAMSTEC

Interannual-to-decadal variability in the tropical Atlantic is dominated by two modes of variability. The zonal mode governs in the equatorial Atlantic and is thought to rely on dynamics akin to El Nino-Southern Oscillation (ENSO). The meridional mode, on the other hand, involves sea-surface temperature (SST) anomalies in the northern and southern tropical Atlantic centered at 15^oN and 15^oS, respectively.

In the present study we use the NCEP reanalysis, OFES hindcast, and CSIRO Mk 3.5 coupled GCM to reexamine the dynamics governing the zonal mode. We find that equatorial wind stress forcing and ENSO-like dynamics can explain some of the observed warm events but not all of them. In particular there are warm events that occur despite easterly surface wind anomalies in the preceding months. This is due to sub-surface warm waters being advected from approximately 5^oN toward the equator. The sub-surface warming is ultimately related to SST anomalies in the northern tropical Atlantic, which induce wind stress curl anomalies that force downwelling just north of the equator. This suggests a mechanism by which off-equatorial ocean conditions can influence the zonal mode of variability and poses an additional challenge to skillful predictions in the region.

Using observational and reanalysis data, the mechanism of a new climate mode off western Australia called ”Ningaloo Nino” is investigated. It is associated with positive sea surface temperature (SST) anomalies and peaks during austral summer. There are two types of Ningaloo Nino: The ”locally amplified” and ”non-locally amplified” events. The former can develop through an intrinsic unstable air-sea interaction off western Australia; an anomalous cyclone generated by positive SST anomalies forces northerly alongshore wind anomalies, which induce coastal downwelling anomalies, and enhance the warm SST anomalies.

It is found that the locally amplified Ningaloo Nino cause positive rainfall anomalies along the coast of western Australia, but the signals are subtle and the northern part tends to become drier because of a weaker monsoon.

全休気候モデル（GCM）における El Nino-Southern Oscillation (ENSO) のシミュレーションは、近年改善が著しい。しかし、依然として ENSO の振幅にはモデル間で大きなばらつきがあり、最近の CMIP5 でも本質的には変わっていない。このことは、ENSO の複雑なフィードバックの誤差要因を詳しく理解する必要性を示している。一方で、ENSO が過去どのように変遷してきたか、また将来の温暖化した気候で変化するか否かは社会的にも大きな問題であり、不完全な GCM を用いてこの疑問にどこまで答えることができるかは、まさに我々研究者の腕の見せ所である。本公演では、こうした GCM における ENSO の特徴を簡単にレビューし、ENSO の変化について最近の研究成果を紹介する。

熱帯太平洋上で発生するエルニーニョ・南方振動（ENSO）は、大気の橋を介して世界中に影響をもたらす大気海洋結合系の代表的な気候変動モードである。これまでに、ENSO の経年変動メカニズムを説明するために、幾つかの振動モデル（振動子理論）が考えられており、その線形的な発達・衰弱・遷移の振る舞いに関しては既に先行研究において説明がなされている。しかしながら実際の観測結果では、正位相から負位相への遷移は急速に進行するのに対し、負位相から正位相への遷移では多くのイベントで停滞する傾向があり、このような遷移プロセスの差異について従来の振動子理論では説明が困難であった。また、既存の気候モデルなど多くの全球大気海洋結合モデルでは、この遷移の非対称性がうまく再現できておらず線形的（正弦波的）な振動を示し、ENSO イベントの頻度増加や ENSO の予測精度が春に著しく低下する原因となっている。この ENSO の遷移プロセスの差違に対し、大気海洋結合の観点から物理メカニズムとモデルバイアスの原因解明・改善方法の検討が望まれている。

これまでの研究で、ENSO の非対称性はエルニーニョ時とラニーニャ時の大気の非線形的な応答によって発生しており (Ohba and Ueda 2009)、インド洋の海面水温変動がそれをさらに強化していることがわかってきた (Okumra et al. 2011; Ohba and Watanabe 2011)。また、CMIP3（結合モデル相互比較プロジェクト）のデータを用いたモデル間の比較により、中央赤道太平洋上の降水活動の基本場の季節性や強度が ENSO の非対称性の再現性と関係していることが示されている (Ohba et al. 2010)。発表ではこれまでの研究をまとめるとともに、過去 100 年の長期変化の傾向や予測精度の非対称性など、今後の課題についても紹介する予定である。

In line with the experimental design for near-term climate prediction toward the 5th Assessment Report of the Intergovernmental Panel on Climate Change, we performed ensembles of initialized decadal hindcast and near-future (NF) projection using three versions of the coupled atmosphere-ocean model MIROC. In this study, interannual and multiyear predictability of tropical cyclone (TC) activity in the western North Pacific (WNP) is explored, using the initialized hindcasts. In addition, global warming impacts on WNP TC activity in the NF are also examined using the NF projection up to 2035.

The hindcasts show that year-to-year variation of TC number reasonably captures the observation. Interannual variability for TC genesis and occurrence frequency (TGF and TOF) associated with ElNino Southern Oscillation (ENSO) is found to be predictable mainly through better prediction of sea surface temperature (SST) and lower-tropospheric large-scale vorticity anomalies. These results indicate that models are able to reproduce the major basic mechanisms that link TC genesis with large-scale circulation. On the multiyear timescale, skillful prediction of TC number is likely difficult at least in our hindcasts, but three-year-mean states of hindcast started in 1998 reasonably capture observed major characteristics of TC activity associated with the Pacific climate shift during the late 1990s through the initialization.

Projected NF (2016-2035) change in WNP TC genesis number shows significant reduction (approximately 14%) especially over the western WNP even in the NF when the global warming is not so prominent compared with the end of this century. The reduction is likely due to the suppression of large-scale lower-tropospheric vorticity and relative humidity, and enhancement of vertical wind shear. The projected SST exhibits a more pronounced warming over the eastern tropical Pacific and accompanies weakening of Walker circulation via redistribution of tropical convection activity, which appears to be responsible for the change in large-scale fields in WNP.

A suite of ship observations including sea level pressure, marine cloud, surface wind, and ocean subsurface temperature show that the Walker circulation has slowed down for the past century. The cause of this slowdown is investigated using a multi-model ensemble of atmospheric GCM simulations forced by several datasets of historical SST. The models reproduce observed changes well if the right SST datasets are used. The results show that the Walker circulation change over the past six decades was induced mostly by changes in zonal SST gradient across the Indo-Pacific Oceans, and that the warming over the Indo-western Pacific is not as large as previously thought. The widely-used SST datasets show intense warming over the tropical Indo-western Pacific, where uncertainty of SST warming trend is especially large. As a result, atmospheric GCMs forced by the conventional SST datasets tend to strengthen the Walker circulation, in disagreement with observations. The observed circulation change over the tropical Pacific contains large natural variability but provides a useful constraint on historical SST reconstruction.

The motivation of this study is to evaluate SST variations of Coupled Model Intercomparison Project (CMIP5) dataset in Eastern Equatorial Indian Ocean (EEIO) by considering the influence of subsurface ocean structure. Variations of SST are studied by applying Power spectral density (PSD) analysis on SST of CMIP5 dataset and observation of SODA dataset. Some models show stronger/weaker SST variations than observation on specific time scale. Based on the strength of SST variations relative to observation, models are divided into three groups: strong model, moderate model and normal model. Normal models have SST variations close to observation, while strong and moderate models show stronger SST variations (relative to observation) on 1-2 years, 2-3 years and 3-7 years time scale.

The cause of strong SST variations on 3-7 years time scale is related to shallow thermocline of models. Strong linearity in SST-thermocline relation may indicates more dominant influence of subsurface to SST variations on this time scale. In warming climate, relationship between thermocline and SST is still maintained; models with shallow thermocline shows stronger SST variations than models with deeper thermocline. Many models show unchanged thermocline depth, which may become the cause of a little change in SST variations on 3-7 years time scale.

The trends and various interannual variability components in the tropical tropopause layer (TTL) over the tropics (15oS-15oN) are examined by employing upper air data from GPS Radio Occultation (RO), radiosonde (IGRA, RICH and HadAT2) and ERA-Interim during 2001-2010. The detection capability of the GPS RO, though with limited data coverage, has been shown in previous studies. The temperature anomalies from unadjusted radiosonde (IGRA), adjusted radiosonde (RICH and HaAT2), and ERA-Interim shows favorable comparison with GPS RO except at 100 hPa in ERA-Interim data. Detail analysis of the warming observed in the TTL during 2001-2010 using both standard linear and multiple regressions is carried out. The temperature trend estimated using standard linear regression analysis (i.e. allowing the contributions from various interannual variability) reveals a strong warming of about 0.5-1.5 K/decade in the TTL (about 16-19 km) with maximum warming at about 18 km in each data during 2001-2010. Further, multiple regression analysis is performed while including various interannual components such as Quasi-Biennial Oscillation (QBO), El Nino Southern Oscillation (ENSO) and stratospheric Aerosol Optical Depth (AOD). We performed two types of multiple regression analysis considering without (method-1) and with (method-2) seasonal modulation of the interannual components. The distinct warming in the TTL is partially but not completely removed on removing the QBO and ENSO components. However, on removing the AOD along with QBO, ENSO removes the distinct warming in the TTL. Therefore, this study shows that the strong distinct warming in the TTL is associated with minor volcanic eruptions during 2000s. Positive and significant AOD responses to the temperatures of about 0.1-0.2 K/AOD-Index are observed in the TTL region which explains about 5-15% of the total variance during 2001-2010.

MJO と湿潤ケルビン波の選択に関する環境場
Environmental conditions on the selection of MJO and moist Kelvin waves

古川 達也 [1], 高薮 縁 [1*]
Tatsuya Kogawa[1], Yukari Takayabu[1*]

[1] 東京大学大気海洋研究所
[1]Atmosphere and Ocean Research Institute, University of Tokyo

湿潤ケルビン波とマッデン・ジュリアン振動 (MJO) は、どちらもメソスケールの雲クラスターが総観-惑星スケールに組織化した、赤道上を東進する降水システムである。両者はその東進速度や大気循環の構造が異なるだけでなく、それぞれエルニーニョ南方振動 (ENSO) の別の位相で強く発達することが観測から示されているなど、異なる環境場から影響を受けやすいことが一般的に知られている。本研究では、環境場のどのような違いが湿潤ケルビン波と MJO の強度差に関わるかについて解析し、環境場からの影響の差と関連する擾乱の性質の違いについて考察した。

NOAA の OLR データを用いて東西波数 2-4 の季節内擾乱を取り出し、等価深度の違いによって湿潤ケルビン波と MJO を区別した。環境場は JRA 再解析データを用いて物理量の 3ヶ月平均場と定義した。まず、MJO は季節変化よりもインド洋から西太平洋にかけて偏在する経度依存性が顕著で、対流圏中層の比湿と東西風の鉛直シアの分布と良く対応する。一方で湿潤ケルビン波は 4-6 月に赤道全域で強くなる特徴的な季節変化があり、環境場の海面温度 (SST) 分布との対応が良い。同様に経年変化では、MJO が湿潤ケルビン波より強い年の環境場は海洋大陸から西太平洋で対流圏中層の比湿が大きく (ラニーニャ型)、逆に弱い年はインド洋から海洋大陸で対流圏中層の比湿が小さく、東太平洋で SST が高い (エルニーニョ型) 状態を示した。

次に、擾乱の鉛直構造を比較した結果、MJO は湿潤ケルビン波に比べて対流の後方で下層の収束が深いことを確認した。また、TRMM 2A25 から作成された雨域ごとの降水特性データから、MJO は湿潤ケルビン波に比べて対流性降水より層状性降水の割合が多くより組織化されたメソシステムで構成することが示された。このような対流の性質の差が、主に対流圏中層の比湿といった環境場との対応関係に影響していることが考慮される。

1 Introduction

Natural variabilities of precipitation microstructure (e.g., DSD) substantially limit the accuracy of some DSD applications such as radar-derived rainfall. The aim of the present study is to investigate the intraseasonal variation of precipitation microstructure at Kototabang, west Sumatra, from long term precipitation data record.

2 Data and Methodology

The DSD observation was from a 2D-Video Disdrometer (2DVD), about eight years (end of 2002?2010). The vertical profile of DSD was from 24 GHz Micro Rain Radar (MRR). 1.3 GHz wind profiler data were used to determine the precipitating cloud type. Horizontal distribution of precipitation around 2DVD was observed by using 9 GHz X-band weather radar. Precipitation data were classified into three categories of MJO phase, i.e., (i) active, (ii) inactive/suppressed and (iii) weak MJO. Active and suppressed MJO are strong MJO phase in which the amplitude of MJO is greater than unity. For Kototabang, active convection was assumed when the MJO is during phases 2, 3, 4, and 5, and inactive/suppressed convection was assumed during phases 6-8 and 1. All cases with the amplitude of MJO being less than unity are assumed as weak MJO phase.

3 Results

During light rain, a slight difference in the DSD could be seen in which the DSD during inactive phase had more large drops than during active phase. The evidence of intraseasonal variation of DSD become more obvious during heavy rain in which the DSDs were much broader during inactive than active MJO phases, consistent with the previous study [1, 2]. Figure shows diurnal variation of percentage of rainfall contribution for several rain types during active and inactive MJO phases. During active MJO phase, shallow convective rain was dominant while deep convective rain was dominant during inactive phase. Detailed analysis regarding the intraseasonal variation of precipitation microstructure over Sumatra will be presented in the meeting.

As a part of the CINDY2011/DYNAMO observation campaign, Research Vessel (R/V) Mirai was deployed at 8S, 80.5E in October and November of 2011. In this study, we investigate variability of surface meteorological variables and air-sea fluxes caused by atmospheric cumulus convective activity. Characteristics of convective systems observed by R/V Mirai in first half of October were quite different from those in second half of October and November.

In the former period, four mesoscale convective systems (MCSs) produced most of precipitation around R/V Mirai, associated with large-scale lower-tropospheric cyclonic circulation anomalies. Composite of the four events show that sensible heat flux was increased by approximately 20 W m^{-2} only during the passage of the MCS due to both increase in air-sea temperature difference and increase in surface wind speed. On the other hand, latent heat flux started to increase when the MCS reached the R/V Mirai, and continued to increase even after the passage of the MCS due solely to the increase in the surface wind speed. A difference in latent heat fluxes before and after the MCS events was approximately 70 W m^{-2} on average.

In the latter period, most of the observed convective events were sporadic sub-MCS-scale ones. By detecting sharp drop of surface temperature and its subsequent recovery period, we identify 22 events. Among them, 13 events consisted of only one temperature drop, while the other 9 events consisted of two times of temperature drops. We examine composite behavior of these two groups, as well as individual cases. We compare surface meteorological variables and radar reflectivity data, and find that minimum temperature is well correlated with maximum surface wind and ratio of radar echo area around R/V Mirai. Sensible and latent heat increases averaged for all the events were approximately 15 and 50 W m^{-2}, respectively.

本研究は 5 月下旬から 7 月中旬までの梅雨期において梅雨降水の経年変動偏差の持続性とその変化を調査する。梅雨降水に影響を及ぼす大気循環場は 6 月下旬頃に急激に変化する。この変化前の期間では、主としてエルニーニョ・南方振動（ENSO）による北西太平洋の海水温偏差（SSTAs）が太平洋ー東アジア遠隔応答を通して梅雨降水偏差をコントロールする。この大気循環場は SSTAs によるロスビー波応答によって特徴付けられ、この期間持続する。一方、変化後の期間では、ENSO を通した熱帯インド洋と北西太平洋の SSTAs の共変化が梅雨降水に重要となる。熱帯インド洋における SSTAs のケルビン波応答を通した大気循環偏差場が北西太平洋に形成される。この応答は北西太平洋高気圧の季節的な北進と一致する必要があるため、変化後の期間にのみ梅雨降水への影響が現れる。このため、二期間の梅雨降水の経年変動は時空間的に有意な相関をもたない。これらの結果は北西太平洋とインド洋における SSTAs のモニタリングが梅雨期間全体の降水の予測可能性を向上させることを示唆する。

Atmospheric forcing from Madden-Julian Oscillation (MJO) produces sea surface temperature (SST) variation on intraseasonal timescales in the tropical Indian Ocean. In this study, we investigate the ocean mixed layer temperature variation in the eastern Indian Ocean to clarify the processes that produced the intraseasonal SST variation. We used mooring buoy data from the Research Moored Array for African-Asian-Australian Monsoon Analysis and Prediction (RAMA) in the Indian Ocean, particularly on an eastern site at 1.5S, 90E. We focused on intraseasonal SST cooling events as an indicator of the intraseasonal variation. The buoy observation captured 14 MJO events in the Indian Ocean from November to May during 2002-2007. In general, the events accompany by large-scale SST decreases in the central and eastern Indian Ocean with the onset of atmospheric convection and westerly winds. Mixed layer temperature balance analysis demonstrated that the intraseasonal SST variation was mainly produced by surface heat fluxes, in which suppressed shortwave radiation and enhanced latent heat loss had major roles. Horizontal heat advection also acted to cool mixed layer temperature during the period, though the contribution was less than one third of the net surface heat flux. Deepening of mixed layer and low salinity signal were also observed during the events. Possible impacts of the ocean variability on the mixed layer heat content are discussed.

In this paper we use sea surface height (SSH) derived from satellite altimetry and an analytical linear equatorial wave model to interpret the evolution of the Indian Ocean Dipole (IOD) in the framework of recharge oscillator theory. The specific question we address is whether heat content in the equatorial band, for which SSH is a proxy, is a predictor of IOD development as it is for El Nino and the Southern Oscillation (ENSO) in the Pacific. We find that, as in the Pacific, there are zonally coherent changes in heat content along the equator prior to the onset of IOD events. These changes in heat content are modulated by wind-forced westward propagating Rossby waves in the latitude band 5-10S, which at the western boundary reflect into Kelvin waves trapped to the equator. The biennial character of the IOD is affected by this cycling of wave energy between the equator and 5-10S. Heat content changes are a weaker leading indicator of IOD sea surface temperature anomaly development than is the case for ENSO in the Pacific though because other factors are at work in generating IOD variability, one of which is ENSO forcing itself through changes in the Walker Circulation.

Southern African summer rainfall simulated in three versions of an atmospheric general circulation model differing only in the convection scheme is examined with a special focus on tropical temperate troughs (TTTs). All three versions provide satisfactory simulations of key aspects of the summer (November-February) rainfall, such as the spatial distribution of total rainfall and the percentage of rainfall associated with TTTs. However, one version has a large bias in the onset of the rainy season. Results from self-organizing map (SOM) analysis on daily precipitation data revealed that this is because the occurrence of TTTs is underestimated in November. This model bias is not related to westerly wind shear that provides favorable condition for the development of TTTs. Rather, it is related to excessive upper level convergence and associated subsidence over southern Africa, which is forced by strong convection in the far western tropical Pacific.

Furthermore, the models are shown to be successful in capturing drier (wetter) conditions over the southern African region in El Nino (La Nina) years. The SOM analysis reveals that nodes associated with TTTs in the southern (northern) part of the domain are observed less (more) often during El Nino years, while nodes associated with TTTs occur more frequently during La Nina years. Also, nodes with dry condition over southern Africa are more (less) frequently observed during El Nino (La Nina) years. The models tend to perform better for La Nina, because they are more successful in capturing the frequency of different synoptic patterns.

We explore causes of less skills in hindcasting recent decadal climate changes, such as the Pacific decadal variability and the so-called hiatus of global warming tendency in the 2000s. As the hiatus forms a negative Pacific Decadal Oscillation (PDO)-like spatial pattern, together with the warming tendency in the extratropical North Atlantic relating to the Atlantic Multidecadal Oscillation and the strong temperature rising in the Indian Ocean, here we focus on the sea surface temperature (SST) tendency in the Pacific and on possible remote influences from other oceans. The Pacific decadal variability is generally regarded as an internal fluctuation in the climate system and, when statistically analyzing sets of initialized decadal hindcasts for recent decades, errors in initial state of the tropical Pacific SST can control skills in predicting extratropical SST variability relating to the PDO. By performing some sensitivity experiments using global climate models, in addition, we also find small but significant impacts of the other oceans on some stages of the Pacific decadal variability. While our ability to predict decadal variations in each ocean is limited at this stage, except for the high latitude of the North Atlantic, further understanding of these remote influences in addition to the inherent decadal fluctuations over the Pacific Ocean can help us to enhance the predictability of decadal climate changes.

Temporal variations of monthly sea surface temperature (SST) anomalies from 1951 to 2012 are investigated using observational dataset (ERSST: Smith et al., 2008). To explore large-scale SST patterns, we perform an empirical orthogonal function (EOF) analysis in the South Indian Ocean [20E-120E, 55S-Equator]. The first EOF mode (35%) represents an increasing tendency and the second EOF mode (13%) presents the Indian Ocean subtropical dipole (IOSD) pattern, as shown by Behera and Yamagata (2003). The third EOF mode (9%) has an east-west seesaw pattern, whose boundary lies at 90E: the centers of action are located around [70E, 30S] in the positive area and [110E, 30S] in the negative area. The time coefficient tends to have low-frequency variations: positive phases in the 1970s and 2000s, and negative phases in the 1960s and 1990s.

We specifically focus on the third EOF mode. We propose an zonal dipole index (ZDI) showing an activity of the third EOF mode based on the SST anomalies: the ZDI is defined as the SST anomalies averaged within the central South Indian Ocean [65E-75E, 35S-25S] minus SST anomalies averaged within the eastern side of the basin [110E-120E, 35S-25S], and then the ZDI is normalized using a standard deviation. Because the correlation coefficient between the ZDI and the time coefficient of the third EOF mode is 0.80, results obtained using the ZDI are not substantially different. We investigate temporal feature of the ZDI by applying a power spectral analysis. Result shows that the dipole SST pattern has a low-frequency variation on decadal (about 15 years) timescale. In addition, we investigate monthly dependence of the zonal SST pattern using the root mean square. Result shows that the SST pattern is dominant during austral summer (January to March).

We investigate causes of the zonal dipole SST pattern by applying a correlation analysis for various variables such as SST, sea level pressure (SLP), sea surface wind, and vertical velocity through the troposphere. Here, we use the JFM mean values. The correlation analysis with the ZDI shows existence of positive SLP anomaly with the downward anomaly located around [90E, 20S]. Therefore, we can point out that the zonal dipole SST pattern results from changes in surface wind related to the SLP variations. Interestingly, the ZDI shows significant correlations in the western equatorial Pacific: positive SST pattern, negative SLP pattern, and upward anomaly throughout the troposphere. The SST spatial structure resembles the El-Nino Modoki: an obtained coefficient between the ZDI and the Modoki index is 0.30 (0.54 of 1981-2012). Therefore, we expect that changes in zonal atmospheric circulation, that is, Walker circulation, associated with the western equatorial Pacific SST variations can form the zonal dipole SST pattern in the South Indian Ocean.
