We have the POSEIDON seismic network which covers the western Pacific area. This area is the most seismically active area in which many big shallow earthquakes occur. However, this network is composed of different observation systems, as a result, the data format of these records are different at each of the station. Because of this, it is not convenient for using the data. We replaced the observation system of all of the POSEIDON stations with newly developed systems and renamed to OHP Seismic Network.
