The Magnetospheric Specification Model (MSM) provides retrospective and real-time maps of particle fluxes in the inner magnetosphere.

The MSM uses an empirical electric field model sorted by Kp index. It is possible for the KRM algorithm, however, to provide temporal development of distribution of the electric potential using ground magnetic data, which is mapped along magnetic field lines into the equatorial plane of the magnetosphere.

Then we adopted the electric field model calculated by using the KRM algorithm as input data of the MSM.

The Magnetospheric Specification Model (MSM) provides retrospective and real-time maps of particle fluxes in the inner magnetosphere.

The MSM uses an empirical electric field model sorted by Kp index. It is possible for the KRM algorithm, however, to provide temporal development of distribution of the electric potential using ground magnetic data, which is mapped along magnetic field lines into the equatorial plane of the magnetosphere. Then we adopted the electric field model calculated by using the KRM algorithm as input data of the MSM. This was applied to a substorm event that occurred on January 10, 1997, whose expansion onset occurred at 0338 UT.

The results represented the temporal evolution of distribution of particle fluxes, which we could not derive in the case that the MSM used the empirical electric field model.
