Numerical weather simulation toward tera-computing

Chiashi Muroi[1]

[1] Numerical Prediction Division, Japan Meteorological Agency

   Development of computational technology gives us a motivation to integrate a huge system of numerical weather simulation which is essential for weather forecast and research of climate prediction.In particular, parallel computing become conspicuous lately and technique of numerical simulation will be important. "Earth simulator" will sustain 40Tflops. Development of utilization of huge parallel computing is required.
   Future issues for these development will be efficient parallel algorithm, increase of transport speed between main memories and treatment of huge amount of data.
   JMA operates global model and regional model for numerical weather prediction. Specifications, results and future requirements will be described.

   Recent development of computational technology gives us a motivation to integrate a huge and complex system of numerical simulation of meteorological phenomena which is essential for weather forecast and research of climate prediction. In particular, parallel computing become conspicuous lately and technique of numerical simulation will be much more important. "Earth simulator" project which is promoted by Ministry of Education, Culture, Sports, Science and Technology in Japan will sustain 40Tflops. Development of utilization of huge parallel computing is required.
   Future issues for these development will be efficient parallel algorithm, increase of transport speed between main memories and treatment of huge amount of data.
   JMA operates global model and regional model for numerical weather prediction. Specifications, results and future requirements will be described.
