

Airglow continuum imaging by wide-field CCD camera

Ryosuke Nakamura[1]

[1] NASDA/EORC

I present the motivation and the results of the wide-field imaging of the airglow continuum emission around 480 nm.

Accurate measurements of the absolute brightness and temporal/spatial variations are expected to provide unique and important information on the dynamics and chemistry of lower thermospheric NO, $\{\text{rm NO}\}_{2}$ and atomic oxygen.

In addition, extra-terrestrial sky brightness and scattering properties of aerosol particles will be obtained as byproducts.
