

## Chemical evolution of the solar system and bulk chemical composition of the earth system

# Hiroko Nagahara[1]

[1] Geol. Inst., Univ. Tokyo

Evolution of the solar system is controlled by the movement of gas and dust accompanying evaporation and condensation with the change of the ambient temperature and pressure conditions. Most of previous work concentrates either on the physical aspect or chemical aspect. Models combining physical and chemical processes have been recently developed. Recent trials are reviewed and its relationship to the bulk chemical composition is discussed.
