

## Desorption of the Charged Particles from the Lunar Surface and the Lunar Exosphere

# Shoichiro Yokata[1], Yoshifumi Saito[1], Kazushi Asamura[1], Toshifumi Mukai[1]

[1] ISAS

Since the Moon has no global magnetic field and only a tenuous atmosphere, solar wind ions directly bombard the lunar surface, sputtering atoms and secondary ions from the exposed grains of the regolith. Sputtered ions and photoionized atoms are picked-up by the interplanetary magnetic field. The ion energy mass spectrometer onboard the SELENE satellite will measure the 3D distribution function of mass-discriminated ions around the Moon. We will report the results of the numerical calculation of the Moon-originated ion flux which is expected to be observed at the SELENE satellite's orbit.
