We report variability of near-infrared reflectance of Jupiter during 1994-1999. The observations are carried out at the wavelengths of 2.12 and 2.35 micrometer

using near-infrared imaging (and spectroscopic) device, OASIS, attached on the 188-cm telescope of the Okayama Astrophysical Observatory, NAO. Some reduced images for 1994-1999 are scanned along the central meridian of Jupiter. During 1994-1999, there are a little changes of reflectances of Jupiter, except the impact latitude of comet SL9.
