From our previous studies with various observations and numerical simulations, ionospheric irregularities in the midlatitude E region have been known to be strongly related with polarization electric field generated in sporadic-E (Es) layers. Neutral wind shear or atmospheric gravity waves can produce such strong polarization field. On the other hand, medium-scale traveling ionospheric disturbance (MSTID) observed in the midlatitude F region in nighttime is also considered to be associated with electric fields. While the Perkins instability is the most plausible mechanism of MSTID, the growth rate of the instability is very small and cannot explain the observed disturbances. Recently, it is proposed that the electrical coupling between the E and F regions can increase the growth rate of the Perkins instability. We study this coupling effect with a three-dimensional numerical simulation. We will show that the polarization electric field generated in Es layers can map up to the F region and seed the Perkins instability effectively. Polarization electric field produced by gravity waves may also have significant effect on the midlatitude F-region dynamics.
