### 1. $^{14}\text{C}$ age and calendar date

Radiocarbon ( $^{14}\text{C}$ ) dating is based on present concentration of  $^{14}\text{C}$  atom which was incorporated into a sample together with stable carbon isotopes,  $^{12}\text{C}$  and  $^{13}\text{C}$ , at the time of its formation. The production rate of  $^{14}\text{C}$  has been changed due to modulations of intensity of cosmic rays coming into atmosphere, by temporal variations of geomagnetic intensity and solar activities. The fluctuations of  $^{14}\text{C}$  abundance in the atmosphere have been revealed by using annual rings of trees, which have preserved atmospheric  $\text{CO}_2$  in the past by carbon fixation through photosynthesis. Up to now,  $^{14}\text{C}$  variations in atmospheric  $\text{CO}_2$  have been established for nearly 12,400 yr by using annual rings of huge trees collected from some limited areas in the world. The  $^{14}\text{C}$  variation records are extremely important now to translate  $^{14}\text{C}$  ages measured for geological and archeological samples to calendar dates. For the translation, normally named as calibration, of the temporal scale, IntCal98 (Stuiver et al. 1998) or IntCal04 (Reimer et al. 2004) data sets are used widely. Recently, most of  $^{14}\text{C}$  ages for archeological and geological samples are calibrated to calendar years for chronological discussion, in particular for those with calibrated ages younger than 26,000 cal BP.

### 2. $^{14}\text{C}$ wiggle matching

A  $^{14}\text{C}$  wiggle matching normally use  $^{14}\text{C}$  ages of more than several annual rings of a sample tree. As described above, radiocarbon community possesses internationally accepted data sets that describe a general relation between  $^{14}\text{C}$  ages and tree ring ages, known as IntCal98 and IntCal04. Taking account of the age gaps of successive  $^{14}\text{C}$ -analyzed rings of a sample tree, the respective sample  $^{14}\text{C}$  ages are compared with the ones of the IntCal98 or IntCal04 calibration data set, by shifting the annual ring number on the calibrated age axis, and finally the calendar age of the outer most ring of the wood is determined. Up to now,  $^{14}\text{C}$  wiggle matching has been applied to determine accurate ages of tree woods for the studies on volcanology, archeology and cultural-property sciences.

### 3. Application of $^{14}\text{C}$ wiggle matching

As an example of  $^{14}\text{C}$  wiggle matching applications, a charred wood trunk collected from a pyroclastic flow deposit produced in the 10th century on the foot of Baitoushan Volcano, locating on the border between North Korea and the People's Republic of China, was analyzed. The ash layer from volcanic fall accompanied by the deposit is recognized clearly in the northern part of Japan and denoted as B-Tm (Baitoushan-Tomakomai) tephra. A wood sample collected from Baitoushan Volcano in 2001 with 102 annual rings, was used for  $^{14}\text{C}$  dating. The annual rings were divided into 82 pieces.

The 35 charcoal annual-ring samples were processed by acid-alkali-acid treatments and converted to graphite in a routine method. The  $^{14}\text{C}$ ,  $^{13}\text{C}$  and  $^{12}\text{C}$  were measured with a HVEE Tandemron at Nagoya University. The obtained  $^{14}\text{C}$  dates were compared with the IntCal98  $^{14}\text{C}$  calibration data by wiggle matching. We obtained a probability distribution of one clear peak that corresponded to the time when the outermost ring was grown most probably in 935 cal AD, with uncertainty of +8 and -5 yr for 95% confidence.
