The Tokyo and Nakagawa Lowlands are underlain by the Latest Pleistocene to Holocene strata, called as Chuseki-so deposits, filling a buried incised valley formed during the last glacial age. The science project has been doing as follows;

1) establishing the standard of stratigraphy and physical property of the Chuseki-so deposits, 2) collecting about 20000 numbers of existing borehole log data surveyed for building construction and establishing a 3-D geological structural model.

We will introduce the recent study results at the sixth year and the outline of future science project plan.
