Extremely small growth and dissolution rate measurements are needed for the estimation of carbon sequestration, the rate of which has been measured by varieties of methods. Among others, advanced phase-shift interferometry has an advantage to measure the rate as small as 10-5nm/s. Some approach has been conducted to investigate coupled dissolution and precipitation mechanism related to carbon sequestration using this sophisticated technique.

キーワード:結晶成長, CO2削減,溶解速度,成長速度,その場観察

Keywords: crystal growth, carbon sequestration, disolution tate, growth rate, in situ observation
