ISS-IMAP (Ionosphere, Mesosphere, upper Atmosphere, and Plasmasphere mapping) mission is a space-borne imaging mission to elucidate the Earth upper atmosphere, the mesosphere, the ionosphere, the thermosphere and the plasmasphere. It is a scientific mission that uses two imaging instruments on the Exposed Facility of Japanese Experiment Module on the International Space Station, EF of ISS-JEM. The development of the scientific instruments have been completed in 2011. The observation is planed to be started in 2012. It will make imaging observation of the Earth’s upper atmosphere with visible-light and infrared spectrum imager (VISI) and extra ultraviolet imager (EUVI). The objective of this mission is to clarify the physical mechanism of the following three processes: (1) energy transport process by the atmospheric structures whose horizontal scale is 50-500km in the upper atmosphere (2) process of the plasma transport up to 20,000km altitude (3) effect of the upper atmosphere on the space-borne engineering system. ISS-IMAP will measure the following three parameters in the lower latitude region than 50 degrees: (1) distribution of the atmospheric gravity wave in the mesopause (87km), the ionospheric E-region (95km), and the ionospheric F-region (250km) (2) distribution of the ionized atmosphere in the ionospheric F-region (3) distribution of O⁺ and He⁺ ions in the ionosphere and plasmasphere. VISI will observe the airglow of 730nm (OH, Alt. 85km), 762nm (O₂, Alt 95km), 630nm (O, Alt. 250km) in the Nadir direction. EUVI will measure the resonant scattering of 30.4nm [He⁺] and 83.4nm [O⁺]. Its field-of-view is 15 degrees, and points the limb of the Earth to observe the vertical distribution of the ions. The scientific objectives and current status of the ISS-IMAP mission will be introduced in the presentation.
