

Sustaining a Community with Social Media

ITO, Masaki^{1*}

¹Tottori University

This paper introduces the way to organize and sustain a community, using social media such as Twitter. The members of the community have different background including computer technology, spatial information science, archaeology etc, and belong to different types of organization such as a university, a company and a public agency. People on the community not only discuss online, but held a meeting to study emerging GIS technologies. This paper introduces technologies and tools that enable organization of such types of community.

Get connected, started, and developed interdisciplinary research with social media: a case study from archaeological GIS

KONDO, Yasuhisa^{1*}, AKO, Takayuki²

¹Dept. Comp. Sci., Tokyo Institute of Technology, ²The Museum, Tokyo Institute of Technology

We reported our Ustream program "Tomobiki Night!!" featured by archaeology and Geographic Information Systems and Sciences (GIS) at the "Social Media and Geoscience" session in JpGU 2011 (http://www2.jpгу.org/meeting/2011/yokou/MTT034-02_E.pdf). By February 15, 2012, the program has been broadcasted for 25 times, on every other *tomobiki* day in Japanese lunar calendar system in theory. A live typically has one to ten viewers, and the recorded videos (<http://ustre.am/fAyw>) have been viewed for 884 times to date.

In addition to reports of academic conferences and workshops associated with archaeological GIS and demonstrations of research instruments, talk sessions to which a guest is invited from the archaeology-related fields of research is the most significant feature of the program among others. We have had five guests from geography and spatial information sciences, and casual talks after the live session have often resulted in a new development of research. For instance, after his participation in the Ustream talk, a researcher in human geography was invited to give a lecture at the special session titled "The Present and Future of Field GIS for Human Science", organized by the first author at the 20th annual conference of GIS Association of Japan in October 2011. Another guest, who was a master student in geography, talked about her dissertation and then she was invited to give a follow-up presentation in an offline meeting after her final examination.

Furthermore, we have provided technical supports of Ustream broadcasting to photography workshops coordinated by Field-net, a social network for field scientists, on the request from a viewer in cultural anthropology. Another viewer in medical GIS, with whom we are frequently communicating via Ustream and Twitter, has become a good collaborator to held GIS workshops and related excursions twice with young researchers and engineers. These events are further developed to a GIS-based multidisciplinary research project of a remote island.

These episodes have a common denominator in which communications through the social media such as Ustream and Twitter encouraged the real academic interactions such as scientific workshops and collaborative projects. It is also noted that the interactions we established, exemplified by those between archaeology, geography, and medical GIS, suggest that such communications may yield developments in research beyond the conventional boundaries of disciplines and interdisciplinary projects. It is also expected to develop a new relationship between geoscience and archaeology, mediated by the social media.

A study of the public relations for disaster prevention from the standpoint of advertising, and some problems of social

SHIBAZAKI, Miyoko^{1*}

¹Osaka City University

There are many potential problems on social networking sites and the many people that use them. Social networking sites can be a great way for younger people to get connected to the public relations for disaster prevention, but there are some dangers. Initially, there are some people who cannot use. They are vulnerable groups in disaster, people with a handicap, elderly people, children, and people who cannot have a computer or a smartphone. Since they cannot use a computer technology, it is difficult for them to join a community, but they tend to produce 'digital divide' by the social stratum. Next, it is different at the time of usually and a disaster.

Of course, by use of social media, there is a big possibility. Therefore, public relations for disaster prevention needs 'Media mix', combination of advertising channels employed in meeting the promotional objectives of a marketing plan or campaign, is major methods of advertising.

Practical use of the social media in IUGONET

KOYAMA, Yukinobu^{1*}, KANEDA, Naoki², YONEDA, Mizuki³, SHINBORI, Atsuki⁴, TANAKA, Yoshimasa⁵, HAYASHI, Hiroo⁴, UMEMURA, Norio⁶, HORI, Tomoaki⁶, ABE, Shuji⁷, MOTOKA, Tetsuo⁵, UENO, Satoru²

¹Graduate School of Science, Kyoto University, ²Kwasan & Hida Obs., Kyoto University, ³PPARC, Tohoku University, ⁴RISH, Kyoto University, ⁵NIPR, ⁶STEL, Nagoya University, ⁷SERC, Kyushu University

The Inter-university Upper Atmosphere Global Observation NETWORK (IUGONET) is a six-year research project of the National Institute of Polar Research, Tohoku University, Nagoya University, Kyoto University, and Kyushu University to clarify the mechanisms of the long-term variations in the upper atmosphere. We have opened to the public our metadata database of ground-based observations of the upper atmosphere (<http://search.iugonet.org/iugonet/>). Moreover, we have released the iUgonet Data Analysis Software. The IUGONET project uses social media, for instance, 1. tweet the progress of our project by using Twitter, 2. public presentation of the demo movies of our data analysis software by using YouTube, 3. real-time distribution of our workshop by using Ustream.

In this presentation, we will explain the practical use of the social media in IUGONET project.

Gathering, analysis, and visualization of meteorological phenomena using social media

KITAMOTO, Asanobu^{1*}

¹National Institute of Informatics, ²JST

Meteorological phenomena have influence on all the people, so it is one of the most popular topics in daily conversations on social media. On the other hand, social media can also be used as a place for reporting emergency information instantly during meteorological hazards such as typhoons, and there has been strong expectation that social media will evolve into an effective platform for collecting and sharing on-site reports for emergency response. Hence this paper focuses on meteorological phenomena and social media, and discusses how we can gather, analyze, and visualize social media based on our experiences.

This paper mainly deals with the case study of four systems, namely "Typhoon Front" (<http://front.eye.tc/>), "Twiphoon" (<http://twiphoon.eye.tc/>), "Typhoon Now!" (<http://typhoonnow.eye.tc/>), and "Futtekitter" (<http://agora.ex.nii.ac.jp/futtekitter/>). We started an experiment of collecting typhoon information from weblogs in 2004, and from Twitter in 2009. These services are based on a "call-based gathering method" that requires user's actions to report events. This method has an advantage of controlling the format and quality of user's reporting, but it has limitation in the amount of information collected due to the necessity of user's active involvement. Hence we employed a "patrol-based gathering method" for "Futtekitter" started in 2012, and build a system that actively gathers information about events without explicit involvement of users. This system increased the amount of information we can collect to the level of several thousand tweets per hour, for instance, during the event of snowfall in Kanto Region.

The problem of a patrol-based gathering method, however, is that we cannot expect users to assign well-organized metadata. This problem is especially apparent in the problem of named entities. For example, which place and what kind of events a tweet is referring to? This kind of metadata is sometimes given by users in the form of hashtags on Twitter, but it is generally difficult to control because there is no single standard for this kind of metadata. To solve this problem, we need to apply natural language processing (NLP) to natural language text for analyzing content, extracting named entities, and integrating them. To realize this process for placenames, we are now developing a geocoding tool, GeoNLP (<http://agora.ex.nii.ac.jp/GeoNLP/>), which can extract place names from text and resolve them to a unique location. This tool still has a problem of accuracy, but the automatic mapping of text is now easier than before.

We built "futtekitter" with functionalities addressed above, and applied it to the gathering, analyzing, and visualizing tweets on rain and snow. By analyzing tweets, to what spatial and temporal resolution we can collect information about rain and snow from social media, and to what degree we can rely on uncertain information? We discuss the result of analysis based on this motivation.

Educational interaction using wiki between teacher and students

MOKUDAI, Kuniyasu^{1*}

¹Pro Natura Foundation Japan

A paper for measuring understanding of students in university lectures, it is often after the class, and only to be returned. In order to increase the educational effect, it is necessary to modification by the faculty of repetition. In this presentation I report the educational practice of using wiki.

Keywords: wiki, internet, education in University
