Nitrogen isotope ratio (delta\textsubscript{15}N) of plant and soil is widely known as an indicator to trace the nitrogen movement in a ecosystem. Based on the global data collection of delta\textsubscript{15}N plant and soil, recent research has focused on the consistent trend of delta\textsubscript{15}N change with regions which has different climate (mean annual precipitation (MAP), mean annual temperature (MAT)) (Austin and Vitousek 1998; Austin and Sala 1999; Schuur and Matson 2001; Amundson et al. 2003). However the reasonable explanation which connects MAP difference, Nitrogen movement difference, and delta\textsubscript{15}N plant and soil difference among ecosystems does not exist so far. This study aims to clarify the above mechanism, and evaluate the water effect on delta\textsubscript{15}N plant and soil. For the purpose we have set the study sites with different water status in several spatial scales; 2 regions which have extremely different MAP, Several sites with different MAP in each region, and several points along a slope which have different degree of nitrogen loss as leaching.

Taiga forest in northern Mongolia and temperate forest in Hokkaido (Japan) were selected as 2 regions. The MAP of study sites ranges 215-353mm, 701-1731mm in Mongolia and Hokkaido, respectively. From 2003 to 2012 the plant leaf (include wood and grass) and soil (0\textsuperscript{-}50cm depth) were collected along the slope per one site, and analyzed for delta\textsubscript{15}N (per-mill vs. Air-N\textsubscript{2}), N content (wt per-cent), soil water content (wt per-cent), extractable nitrate (NO\textsubscript{3}-) and ammonium (NH\textsubscript{4}+) content in soil (mgN gdw\textsuperscript{-}1).

Regional comparison between Mongolia and Hokkaido showed that delta\textsubscript{15}Nleaf had more variability and higher in Mongolia (-6\textsuperscript{-}+6per-mill) than in Hokkaido (-8\textsuperscript{-}0per-mill), although different plant species were compared. With respect to the smaller scale comparison along slope, delta\textsubscript{15}Nleaf decrease from upper to lower slope were observed at 5 of 7 sites in Mongolia, while no change at all sites in Hokkaido. One factor for the regional and slope scale difference in delta\textsubscript{15}Nleaf is nitrogen movement with water flow, however grazing effect in Mongolia should be as another factor. Combined the delta\textsubscript{15}Nleaf result to the other soil data result, we will discuss the water effect on delta\textsubscript{15}N plant, soil and regional difference in nitrogen movement.
