The oxygen isotope ratios $^{17}$O/$^{16}$O and $^{18}$O/$^{16}$O in the solar system are known to show a clear systematic relation. And the relation differs planet by planet. For example, the $^{17}$O/$^{16}$O ratio as a function of $^{18}$O/$^{16}$O ratio in Mars appears to be larger than that in the Earth-Moon system by 0.05 %. This fact indicates that the proto-Earth-Mars matter was so well mixed but with a systematic difference. In such a way, the isotope ratios may provide information about the origin and evolution of the planets. However, $^{17}$O/$^{16}$O ratio in Venus has never been quantified, and may provide further information about the mixing history of the early solar system if measured.

The ratios may be quantified by ground-based CO\textsubscript{2} IR spectroscopic measurements. By assuming a use of IRTF CSHELL spectrometer with a nominal resolution of 40000, we looked for suitable wavenumber regions to quantify the $^{17}$O/$^{18}$O and $^{18}$O/$^{16}$O ratios. The suitable region for the former is found at 2648 cm\textsuperscript{-1} as shown in the figure, and the latter at 4582 cm\textsuperscript{-1}. In the figure, the top two curves show the earth and solar structures disturbing the quantification, and the middle two curves show the Venus C$^{17}$O$^{16}$O and C$^{18}$O$^{16}$O structures indicating a feasibility to quantify the $^{17}$O/$^{18}$O ratio.
