Northwest Africa (NWA) 6704 is a very unusual ungrouped fresh achondrite. It consists of abundant coarse-grained (up to 1.5 mm) low-Ca pyroxene, less abundant olivine, chromite, merrillite and interstitial sodic plagioclase. Minor minerals are awaruite, heazlewoodite, and pentlandite. Raman spectroscopy shows that a majority of the low-Ca pyroxene is orthopyroxene. Bulk major element abundances are nearly chondritic and distinct from those of howardite-eucrite-diogenites. Oxygen isotopic study demonstrated that $^{18}\text{O}/^{16}\text{O}$ and $^{17}\text{O}/^{16}\text{O}$ of this meteorite plot within the acapulcoite-lodranite field, but these meteorites differ in mineralogy and geochemistry. These observations suggest that NWA 6704 originated on a distinct parent body from all other known meteorites. Here we report U-Pb chronology of the unique achondrite NWA 6704.

U-Pb dating was performed on nine 10-20 mg fractions of pyroxene. All fractions were washed 4-5 times in ca. 0.5 ml of 0.5 M HNO₃. Subsequently, the fractions were washed twice with hot 6 M HCl, followed by twice washing with hot 7 M HNO₃. All residues were spiked with mixed ²⁰²Pb-²⁰⁵Pb-²²⁹Th-²³³U-²³⁶U tracer. Spiked residues were digested in a HF+HNO₃ mixture, converted to a soluble form by repeated evaporation with 7 M HNO₃, 6 M HCl, 9 M HBr, and dissolved in 0.3 M HBr. The Pb separation was performed using 0.05 ml of anion exchange resin AG1x8 200-400 mesh. After the Pb separation, U and Th were separated using 0.05 ml of UTEVA resin. Pb isotopes were measured on a TRITON Plus TIMS at the ANU. U and Th isotopic analyses were carried out on a Neptune MC-ICPMS at the Australian National University.

Two residues yielded higher ²⁰⁶Pb/²⁰⁴Pb values (148 and 213) relative to the others (from 344 to 5494). Model ²⁰⁷Pb*/²⁰⁶Pb* dates (assuming primordial Pb as initial Pb, and $^{238}\text{U}/^{235}\text{U}=137.88$) for seven most radiogenic residue analyses with ²⁰⁶Pb/²⁰⁴Pb more than 500 yielded a weighted average of 4563.34 ± 0.32 Ma. The U-Pb discordance of residue analyses range from -3% to -6% for more radiogenic data, and up to -10% for the two residues that contain less radiogenic Pb. A Pb-Pb isochron for the seven radiogenic residues yielded a radiogenic ²⁰⁷Pb/²⁰⁶Pb value (y-intercept of the regression line) of 0.62351 ± 0.00017. This corresponds to a ²⁰⁷Pb/²⁰⁶Pb date of 4563.75 ± 0.41 Ma, assuming a $^{238}\text{U}/^{235}\text{U}=137.88$. Yet this assumption may be invalid likewise for Ca-Al-rich inclusions (CAIs) and basaltic achondrites. Hence, to establish an assumption-free reliable ²⁰⁷Pb/²⁰⁶Pb date, precise $^{238}\text{U}/^{235}\text{U}$ needs to be determined for this meteorite. Using, instead, the $^{238}\text{U}/^{235}\text{U}$ value of 137.79 ± 0.02 (an approximate estimate for most Solar System materials except CAIs), yields the isochron age of 4562.80 ± 0.46 Ma. This age estimate is valid unless $^{238}\text{U}/^{235}\text{U}$ in NWA 6704 is significantly lower than in the angrites and chondrites. Determination of the $^{238}\text{U}/^{235}\text{U}$ is in progress.

The estimated U-Pb age of NWA 6704 is substantially older than those of plutonic angrites, and only marginally younger than those of quenched angrites. NWA 6704 is about 4-5 Ma younger than the CAIs. Considering the old crystallization age, the expected simple geologic history (suggested by nearly concordant U-Pb systems), the mineral assemblage including pyroxene, plagioclase, olivine, chromite and metal, and the considerable sample size (8.4 kg in total), NWA 6704 has the potential to serve as a reliable reference point of various short-lived isotopic chronometers such as ²⁶Al-²⁶Mg, ⁵³Mn-⁵³Cr and ¹⁸²Hf-¹⁸²W chronometers. A new reliable reference point is essential for checking uniform distribution of the short-lived radionuclides and for building a consistent time scale of the early Solar System.
