Three-dimensional asymmetric magnetic reconnection

Satoshi Takeuchi

A kinetic model of asymmetric magnetic reconnection in three-dimensional space is analyzed theoretically and with numerical calculations. Consider the case where the two magnetized plasmas are colliding each other; for example suppose that the plasma shock is propagating through the uniform background plasma.

In order to provide a clear understanding of the magnetic reconnection presented here, we show a simple representation of the model with the cartoon in Fig. 1. PlasmaA is the stationary plasma whose magnetic field is given by $B_1$. PlasmaB is propagating with the velocity $v_s$ in the positive y direction. The electric field of this plasma is given by $E_2 = (v_s/c)B_2$ ($c$ being the velocity of light). The magnitude of the field is smaller than that of the field $B_1$, i.e., $B_1 < B_2$. The crossing angle is defined as the angle between the fields $B_1$ and $B_2$. This angle plays an important role in generating the magnetic neutral sheet. If the crossing angle is greater than a right angle, then the magnetic neutral sheet is created in front of the shock. The resonant particle interacting with the shock is trapped by the neutral sheet. Accordingly such the particle is accelerated by the electric field $E_2$ in the neighborhood of the neutral sheet. If the angle is nearly equal to a right angle, the direction of the acceleration is almost the same as the direction of the magnetic field $B_1$. This is the way of the field-aligned acceleration presented by the author [1]. If the crossing angle is smaller than a right angle, then the magnetic neutral sheet is not created. Therefore the effective energy gain of the particle cannot be expected.

Keywords: asymmetric magnetic reconnection, particle acceleration, plasma shock wave
