The speciation of C-O-H-N volatiles and silicate components in fluids and solubility and solution mechanisms of C-O-H-N volatiles in aluminosilicate melts have been determined experimentally, mostly \textit{in situ} with the sample at high temperature and pressure corresponding to those of the upper mantle, as a function of melt composition and redox conditions. In silicate-O-H systems, molecular H\textsubscript{2}O and OH groups linked to the silicate network exist in silicate and aluminosilicate-saturated fluids and in water-saturated melts.

The \( \Delta H \) of the water speciation equilibrium, H\textsubscript{2}O+O=2OH, is \( \sim 30 \) kJ/mol. The \( \Delta H \) of hydrogen bonding is \( \sim 10 \) and \( \sim 20 \) kJ/mol for melt and fluid, respectively. Hydrogen bonding is not detected above about 500 deg C. Silicate speciation in fluid and in melt comprises similar Q-species with \( \Delta H \) of the solution reaction \( \sim 400 \) kJ/mol. In silicate-C-O-H systems, under oxidizing conditions (such as that controlled by the magnetite-hematite, MH, buffer, for example) the CO\textsubscript{2} solubility in melts, where it exists as molecular CO\textsubscript{2} and CO\textsubscript{3} groups, is in the 1-4wt% range between \( \sim 1 \) and 3 GPA and upper mantle temperatures. Its solution mechanism is CO\textsubscript{2}+Q\textsubscript{n}=CO\textsubscript{3} +Q\textsubscript{n+1}. This equilibrium probably shifts to the right with temperature and left with pressure \cite{1}. Alkalis and alkaline earths dissolve in C-O-H fluid as complexes with CO\textsubscript{3}. Silicate is not detectable in CO\textsubscript{2} fluid. Methane, CH\textsubscript{4}, is the dominant C-species in melts at \( f_{H_2} \geq MW \) (magnetite-wustite), whereas in fluids, more reducing conditions [iron-wustite (IW) buffer] are necessary to form detectable CH\textsubscript{4}. Methane solubility in melts is 10-30% of that of CO\textsubscript{2}. At \( f_{H_2} (IW) \) the dominant fluid species are CH\textsubscript{4}+H\textsubscript{2}+H\textsubscript{2}O. In coexisting melt, CH\textsubscript{4} groups linked to the silicate melt structure via Si-CH\textsubscript{3} bonding coexist with molecular CH\textsubscript{4} with a solution mechanism, CH\textsubscript{4}+Q\textsubscript{1}=CH\textsubscript{3}+Q\textsubscript{0}. The C(melt)/C(fluid) partition coefficient is in the 0.01-0.1 range with a \( \Delta H \)-value near 50 kJ/mol. In silicate-NOH systems, under oxidizing conditions \( f_{H_2} (MH) \) nitrogen exists principally as N\textsubscript{2}. Under reducing conditions, \( f_{H_2} (MW) \), the nitrogen oxidation state is lowered with NH\textsubscript{3}+NH\textsubscript{2}\textsuperscript{+} groups dominating in fluid and melt. At the more reducing \( f_{H_2} (IW) \) condition, NH\textsubscript{3}+NH\textsubscript{2}\textsuperscript{+} fluid coexisting with NH\textsubscript{3}+NH\textsubscript{2}\textsuperscript{+}+H\textsubscript{2}+H\textsubscript{2}O species in melt with the ammine groups bonded directly to Si\textsuperscript{4+} (Si-NH\textsubscript{2}) and solution mechanism, NH\textsubscript{3}+Q\textsubscript{1}=NH\textsubscript{2}+Q\textsubscript{0}. The N(melt)/N(fluid) is \( \leq 0.1 \) with a delta H near 50 kJ/mol. The nitrogen solubility under these conditions are 2-3 times greater than for oxidized nitrogen.

The \( f_{H_2} \)-dependent speciation C-O-H-N volatile components result in \( f_{H_2} \)-dependent thermodynamic and transport properties of fluids and melts in the interior of the Earth and terrestrial planets. Reduced and oxidized C-O-H-N species exist fluids and melts in the modern mantle, whereas reduced species dominated in the young Earth. In fluids, the solubility of nominally incompatible trace elements can increase by orders of magnitude upon its saturation with silicate components. Trace element and stable isotope partitioning between fluids and melt can change by >100% for the same reason. Dissolved C-O-H-N volatile components in melts can have similar effects. Silicate solute in C-O-H-N fluids also governs the fluid and melt equation of state. For example, dissolved silicate in fluid can increase its density by \( \geq 20\% \) compared with pure H\textsubscript{2}O at 1 GPA.
