Crystal structures of Zn$_2$GeO$_4$ spinel and Zn$_2$SiO$_4$ modified spinel phases

Masami Kanzaki$^{1,*}$, Xianyu Xue$^1$

$^1$Inst. Study Earth’s Interior, Okayama U.

High pressure phase relations of Zn$_2$GeO$_4$ and Zn$_2$SiO$_4$ were studied in 1960s to 1970s (e.g., Syono et al., 1971) in relation to high-pressure mantle minerals, but the crystal structures of high pressure phases discovered have not been determined, except for phase II of Zn$_2$SiO$_4$. In last year’s JPGU meeting, we reported the structures of phase III and IV of Zn$_2$SiO$_4$ (SIT02-24). Here, we report the crystal structures of cubic and tetragonal spinels in Zn$_2$GeO$_4$ and phase V of Zn$_2$SiO$_4$, and also present new structural insights regarding phase III and IV of Zn$_2$SiO$_4$.

All samples were synthesized using 500ton Kawai-type multianvil press at Misasa. Starting materials were Zn$_2$GeO$_4$ and Zn$_2$SiO$_4$ phenacite phases synthesized at ambient pressure. Powder X-ray diffraction patterns were obtained at BL19B2 of SPring-8 using a large Debye-Scherrer camera. For refinement, the Rietveld method was used (RIETAN-FP). Details of the procedure are same as those of Kanzaki and Xue (2012).

Cubic and tetragonal spinels of Zn$_2$GeO$_4$ were synthesized at 3 GPa and 1600 °C, and 5 GPa and 1200 °C, respectively. As expected, these spinels have inverse-type in which the tetrahedral site is occupied by Zn. For tetragonal spinel, the symmetry is lowered as a result of ordering of Zn and Ge in the octahedral sites. The tetragonal spinel phase is isostructural to Zn$_2$TiO$_4$. Bond distances calculated by Brown’s bond valence agree well with the experimental values from the present study.

For the structures of phase III and IV of Zn$_2$SiO$_4$, after last year’s presentation (SIT02-24), we noted that phase III is isostructural to the high-temperature phase of (Zn$_{1.1}$Li$_{0.6}$Si$_{0.3}$)SiO$_4$ (Liu et al., 2013). The latter structure is related to the olivine structure in that metal cations occupy vacant tetrahedral sites, rather than octahedral sites of the olivine structure, and is referred to as "tetrahedral olivine" by Baur (1980). In phase IV, triclusters made of two ZnO$_4$ and one SiO$_4$ sharing a common oxygen form columns running along the c-direction. Similar columns also exist in phase II, which explains the similar densities of phases II and IV.

We refined crystal structure of phase V of Zn$_2$SiO$_4$, and confirmed that it has a modified spinel structure. Its structural parameters are similar to those of Mg$_2$SiO$_4$ wadsleyite. Octahedral sites are occupied by Zn only, and no Zn/Si disorder was detected. This is consistent with the $^{29}$Si MAS NMR result that revealed a single peak of tetrahedral Si for phase V.
