The densities and sound velocities of the Earth's interior have been known based on the seismological observations, as well-known as Preliminary Reference Earth Model (PREM). Although the Earth's core is regarded as an Fe(-Ni) alloy, its density is lower than that of Fe, and sound velocities of the core could not be explained by those of pure Fe at the core conditions. Therefore, the Earth's core is supposed to contain light elements to explain the density deficit and differences of sound velocities between Fe and the Earth's core. Carbon is one of the most important candidates for light elements in the Earth's core. In this study, we focused on the compression behavior of  $\text{Fe}_3\text{C}$ , which is one of the Fe-carbide. We aimed to discuss the possibility of  $\text{Fe}_3\text{C}$  as the constituent of the Earth's inner core.

We performed in-situ X-ray diffraction experiments using the diamond anvil cell at BL10XU beamline of SPring-8 facility to obtain pressure and volume relations of  $\text{Fe}_3\text{C}$ . We obtained  $P$ - $V$  profiles of  $\text{Fe}_3\text{C}$  at 70~180 GPa, and ~2300 K. The equation of state (EOS) of  $\text{Fe}_3\text{C}$  at high temperature conditions was determined using  $P$ - $V$ - $T$  relationships. Compressional data were fitted by the 3rd-order Birch-Murnaghan EOS at 300 K and the Mie-Grüneisen-Debye EOS at high temperature conditions. The parameters of  $V_0 = 152.13(8)$ ,  $K_0 = 265.1(6)$ ,  $K'_0 = 3.66(1)$ ,  $\theta_0 = 246(84)$ ,  $\gamma_0 = 1.06(7)$  and  $q = 1.5(2)$  were obtained. The density of  $\text{Fe}_3\text{C}$  at inner core condition (assuming 329 GPa and 5000 K) calculated from the EOS was compatible with PREM profiles. Our results indicate that  $\text{Fe}_3\text{C}$  could be dominant in the Earth's inner core.
