The ballooning instability has been investigated as a possible mechanism for triggering the substorm in the magnetosphere. The ballooning mode is destabilized, when the interchange term provided with the pressure gradient and the magnetic curvature overcomes the line bending term causing the shear Alfvén waves. In the magnetosphere-ionosphere (M-I) coupling system in polar regions, on the other hand, the shear Alfvén waves (or the kinetic Alfvén waves) can also be destabilized by the magnetospheric convection, if the ionospheric density change is taken into account with the feedback mechanism [1-3].

In the present study, we have investigated the ballooning and the feedback instabilities in the same theoretical framework. Our linear analysis demonstrates that, as the interchange term increases, the "unstable" shear Alfvén waves with the opposite sign of the real eigenvalues in their lowest harmonic branch collide with each other and transit to the ballooning mode. It implies that competitions and/or interactions between the two instabilities may provide a plausible explanation of auroral breakup triggered through the M-I coupling.
