Regional interactions between multiple subducting slabs have been proposed to explain enigmatic slab kinematics at a number of subduction zones, a pertinent example being the advancing motion (i.e. toward the upper plate) of the Izu-Bonin trench (Cizkova & Bina, 2014). An additional, important example is the rapid pre-collisional plate convergence of India and Eurasia during the Late Cretaceous, which is hypothesized to be due to the existence of two north-dipping subduction zones (e.g. Jagoutz et al., 2015). However, dynamically consistent 3-D numerical models of double subduction have yet to be explored, and so the physics of such double slab systems remain poorly understood. Here we augment fully numerical finite element models (CitcomCU) with semi-analytic subduction models (FAST: updated from Royden & Husson, 2006) to explore how subducting slab kinematics, particularly trench and plate motions, can be affected by the presence of an additional slab, with all of the possible slab dip direction permutations. A second subducting slab gives rise to more complex dynamic pressure and mantle flow fields and, for double slab systems within which the two slabs dip in the same direction (e.g. Izu-Bonin and Ryuku trenches, Late Cretaceous India-Eurasia), an additional slab pull force that is transmitted across the subduction zone interface. While the general relationships among plate velocity, trench velocity, asthenospheric pressure drop, and plate coupling modes are similar to those observed for the single slab case, we find that multiple subducting slabs can interact with each other and indeed induce slab kinematics that deviate significantly from those observed for the equivalent single slab models. Double subduction therefore provides a geodynamic mechanism to induce slab kinematics which differ drastically from those predicted from single slab experimental/modeling studies.

Diagram illustrating the geometry and material properties of the lithosphere and asthenosphere. The lithosphere is divided into three regions: SP (Subduction Plate), MP (Mid Plate), and OP (Oceanic Plate). The SP region is shown with a 70° dip. The MP region is shown with a 500 km thickness. The OP region is shown with a 500 km thickness. The diagram includes various dimensions and material properties.

Material properties and dimensions:

- Lithosphere (L): $\eta_L = 1.4 \times 10^{23} \text{ Pas}$, $\rho_L = 3385 \text{ kg/m}^3$
- Asthenosphere (m): $\eta_m = 2.8 \times 10^{20} \text{ Pas}$, $\rho_m = 3300 \text{ kg/m}^3$
- Dimensions:
 - Top surface: FS, $T = T_0$, 7920 km
 - Right side: 2640 km
 - Bottom surface: FS, $T = T_m$, 660 km
 - Left side: 25 km, 1000 km
 - SP region: 2000 km
 - MP region: 2000 km
 - OP region: 2000 km
 - SP dip: 70°
 - MP thickness: 500 km
 - OP thickness: 500 km
 - Right side offset: 80 km
- Boundary conditions: FS, $q = 0$ (Free Surface, zero heat flux)

Figure 10 consists of two panels showing pressure and velocity fields. The top panel is a cross-section at $z = 200$ km, showing a central red region (high pressure) and blue regions (low pressure) with arrows indicating flow direction. The bottom panel is a cross-section at $y = 0$, showing a central red region (high pressure) and blue regions (low pressure) with arrows indicating flow direction. A color bar on the right indicates pressure P [MPa] from -20 to 20. A scale bar at the top right indicates 5 cm/yr.
